Experiment No. 6

Title: Implementation of call centre queue simulation using queue data structure

objective: To implement a queue data structure for simulating a call where in which upcoming call are handled in the data in which they are recieved.

- To understand the concept of
- To add uncoming calls to the queue using add call ().
- To answer & reneve the first call using answer call ().
- To display all waiting call using circle queue()

Theory concept.

Queue:

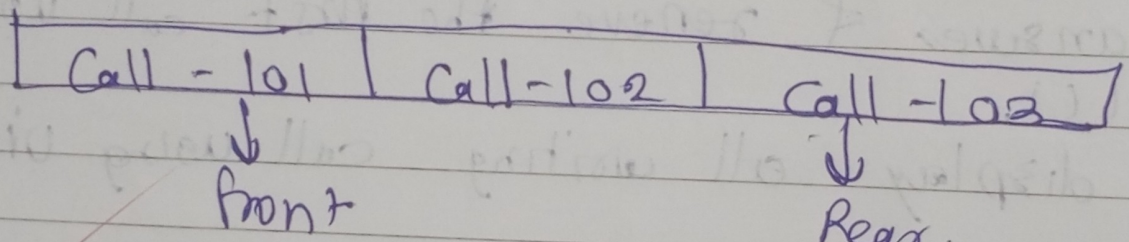

A queue is a linear data structure in which the element are unsetted one end & removed from the other end.

It follows the principle
FIFO - first in first out.

Queue operation

Operations	Description
1. add call ()	Add new call to the rear of q
2. Unique call()	reverse & answer call at
3. view queue ()	display all waiting calls.
4. Is queue empty()	checks whether the q contains any call.

Queue representation:

Call 101 will be answered front.

Conclusion :

The call center queue simulation succesfully demonstrate the practical app are answered in the order they are recieved the system follows the FIFO (first in first out).

The operator add call (), answered (). view queue () & is . Queue empty () , prov the basic functionally , required to mana incoming calls efficiently
